- Please watch a simulation comparing the historical and modern scenario on youtube:  
<http://www.youtube.com/watch?v=eJ5mKFNcfHg>
- The simple explanation is that the global human travel network has become very fast nowadays, basically you can travel anywhere in just a few days at most.

### Introduction

### Epidemic models

#### Homogeneous SIS

#### Inhomogeneous SIS

#### SIR model

### Predicting epidemics

- In this section we review the basic epidemic models studied on networks.
- A common feature of these models is that they assume a few possible discrete states for the nodes describing whether the given node is healthy or infectious.
- The infection can spread over the links, and in the mean time, infected nodes may recover over time in most of the scenarios.

#### SIR model

### Predicting epidemics

- In the following we are going to study the SIS model on networks in an analytic framework.
- We begin with homogeneous networks such as the E-R graph, regular lattices, etc., where it is more easy to introduce the basic concepts such as the spreading rate and the epidemic threshold.
- Once we understand the behaviour in the homogeneous case, we can move onto to in-homogeneous systems such as scale-free networks.

# SIS model on homogeneous networks

## Spreading on networks

Introduction

Epidemic models

Homogeneous SIS

Inhomogeneous SIS

SIR model

Predicting epidemics

## Model assumptions:

- **Homogeneous mixing hypothesis:**
  - The network is homogeneous, (e.g., E-R graph), every node has more or less  $\langle k \rangle$  connections.
  - Every node has the same probability to be linked to an infected one.
- If a susceptible node is attached to an infected one, the probability of transaction per unit time is  $\lambda$ . (Spreading rate)
- For an infected node, the probability of the recovery per unit time is  $\mu$ .
- At  $t = 0$  we start with an infinitesimal  $\rho(t = 0) = \rho_0 \ll 1$  fraction of infected nodes.

The diff. eq. for the time evolution of  $\rho(t)$ :

$$\frac{d\rho}{dt} = \lambda \underbrace{\langle k \rangle}_{\text{linked to I}} \underbrace{\rho}_{\text{S}} (1 - \rho) - \mu \rho$$

S → I

If  $\lambda \langle k \rangle < \mu$ :

# SIS model on homogeneous networks

## Spreading on networks

### Introduction

### Epidemic models

#### Homogeneous SIS

#### Inhomogeneous SIS

#### SIR model

### Predicting epidemics

## EPIDEMIC THRESHOLD:

$$\lambda_c \langle k \rangle = \mu \quad \rightarrow \quad \lambda_c = \frac{\mu}{\langle k \rangle} \quad \leftrightarrow \quad \begin{cases} \lambda > \lambda_c : & \text{exp. outbreak} \\ \lambda < \lambda_c : & \text{exp. decay} \end{cases}$$

For simplicity, let us assume  $\mu = 1$ :

$$\lambda_c \langle k \rangle = 1 \quad \rightarrow \quad \lambda_c = \frac{1}{\langle k \rangle}$$

This becomes very intuitive in discrete time dynamics:

- an infected node recovers in one time step,
- it has  $\langle k \rangle$  neighbors, thus, on average it can infect  $\lambda \langle k \rangle$  other nodes during this time step,
  - if  $\lambda \langle k \rangle < 1$  the infection dies out quickly,
  - if  $\lambda \langle k \rangle > 1$  the infection spreads exponentially.

### Introduction

### Epidemic models

#### Homogeneous SIS

#### Inhomogeneous SIS

#### SIR model

### Predicting epidemics

- Let us now move onto the SIR model.
- In some sense this seems to be more complicated compared to the SIS, since we have 3 possible states (also called as compartments) instead of 2.
- On the other hand, it is more simple in the sense that here everybody must ends up in the R state, unless the disease has died out early.

### Introduction

### Epidemic models

#### Homogeneous SIS

#### Inhomogeneous SIS

#### SIR model

### Predicting epidemics

The basic idea of the GLEAM approach:

- A model with 3 layers, where the bottom layer is corresponding to the population layer, divided into "cells" or regions on the World map, with a number of inhabitants associated to each unit.
- In the middle we have the mobility layer, having two important ingredients:
  - the global airline network,
  - and a local commuting network between neighbouring regions.
- The top layer is corresponding to the disease model we want to study, where we can define compartments such as S, I, R, Endemic, Hospitalised, etc., together with transition probabilities and infection rules.
- For more details please visit the model description part of the GLEAM site:  
<http://www.gleamviz.org/model/>

Predicting epidemics

### Short summary for spreading on networks

- Traditionally we model spreading phenomena by assuming a few states (compartments) describing different stages of the disease such as S, I and R.
- Homogeneous networks have a non-zero epidemic threshold, which means that the spreading rate  $\lambda$  has to be larger than a non-zero constant in order to induce an outbreak, otherwise the infection dies out exponentially.
- However, in the mean time for scale-free networks the epidemic threshold is zero, thus, in principle for any infinitesimally small  $\lambda$  the infection can still prevail. This property is connected to the divergence of the second moment of the degree distribution.
