We have already derived the $p(k)$ of the E-R graph earlier,

$$p(k) = \binom{N-1}{k} p^k (1-p)^{N-1-k} \simeq \binom{N}{k} p^k (1-p)^{N-k} \quad (\text{binomial})$$

$$\simeq \frac{\langle k \rangle^k}{k!} e^{-\langle k \rangle} \quad (\text{Poisson})$$

- What is the **variance** of $p(k)$?

The degree distribution is binomial,

$$p(k) = \binom{N}{k} p^k (1-p)^{N-k},$$

→ the average and variance for a binomial distribution in general is

$$\langle k \rangle = Np,$$

$$\langle k^2 \rangle = Np(1-p) + p^2 N^2,$$

$$\text{Var}(k) = \langle k^2 \rangle - \langle k \rangle^2 = Np(1-p),$$

$$\sigma(k) = \sqrt{\text{Var}(k)} = \sqrt{Np(1-p)}.$$

(For more details about the binomial distribution see e.g.

- Thus, in mathematical terms, the probability for finding nodes with degrees above k_0 can be written as

$$\mathcal{P}(k > k_0) = \sum_{k=k_0+1}^{\infty} p(k) \simeq \int_{k_0}^{\infty} p(k) dk = \int_{k_0}^{\infty} \frac{\langle k \rangle^k}{k!} e^{-\langle k \rangle} dk.$$

- E.g, for $\langle k \rangle = 10$ by evaluating the integral we obtain:
 - the prob. to find a node with $k \geq 20$ is 0.00158826,
 - the prob. to find a node with $k \leq 1$ is 0.00049,
 - the prob. to find a node with $k \geq 100$ is $1.79967152 \times 10^{-13}$.
- According to sociologists, for a typical individual $k \sim 1000$.
 - the prob. to find someone with $k \geq 2000$ is roughly 10^{-27} !
 - A random society would be **extremely homogeneous**, with no outliers!

- What is the clustering coefficient in the E-R graph?
 - The E-R graph is very democratic, and we expect all nodes to have more or less the same C , thus, $C_i \simeq \langle C \rangle$.
 - C_i can be also interpreted as the probability of the neighbors of i being connected. Since in the E-R model we link every pair independently with uniform probability p , the neighbors of any node shall be linked also with probability p .
 - Thus, in the E-R graph $\langle C \rangle = p$.

- The network after the rewiring is very much like an Erdős-Rényi random graph!

→ We can use our knowledge about the E-R graph to calculate $\langle \ell \rangle$ and $\langle C \rangle$.

- The average distance is simply

$$\langle \ell \rangle \simeq \frac{\ln N}{\langle k \rangle} = \frac{\ln N}{2q}.$$

- The average clustering coefficient is equal to the p parameter of the E-R model, which we can obtain based on e.g., the average degree as $2q = \langle k \rangle = (N - 1)p_{\text{ER}}$. Thus, we find

$$\langle C \rangle = p_{\text{ER}} = \frac{2q}{N - 1}.$$

In summary:

- $\beta = 0$:

$$\langle \ell \rangle \simeq \frac{N}{4q}$$

$$\langle C \rangle = C = \frac{q(q-1)^{\frac{3}{2}}}{q(2q-1)} = \frac{3q-3}{4q-2}$$

(A network with high clustering, but definitely not small world).

- $\beta = 1$: E-R model, $G(N,M)$ version.

$$\langle \ell \rangle \sim \log N$$

$$\langle C \rangle = p_{ER} = \frac{2q}{N-1}$$

(A small world network that is definitely not highly clustered).
